AI analysis · Based on Claude self-analysis and deep research

The first-time experience: before, what changed, and what it should do

At Eugene's request, Aurelia was analysed with AI. Claude tested how a brand-new user experiences the app, found what stopped them, suggested fixes and a simpler structure, and built them. They are now live. This page shows the state before, the suggestions, what is in production now, and the expected effect.

Live in production: design v4, commit c58a67a

Based on: retention simulation (25 Oct) and simplification plan (25 Oct)

Analysis and report: Claude (Anthropic's AI), for Werner and Eugene

Taps from typing a problem to hearing a session

~~14~~ **5**

MEASURED same test user, same request

Test users who landed in someone else's conversation

~~5 of 6~~ **0 of 6**

MEASURED on the real app

First sessions built for the user's own goal

~~0 of 6~~ **5 of 5**

MEASURED the 6th now hears a preview instead

New users still active after 7 days

~~3.8%~~ **8.3%**

PREDICTED model, not yet measured

In one paragraph. Before, a new user could reach a session quickly, but in most cases it was not about what they asked for. They saw invented progress before they had listened, and nothing invited them back. Claude fixed those moments, added a simple reason to return (a check-in after each session and a reminder for the next chapter), and reorganised the app into four tabs. All of it is live. The test users now get a session built for their goal in about a third of the taps. Claude's model predicts that roughly twice as many new users will still be active after a week. That forecast is not a measurement yet: it needs a short test with real users.

1. How Claude analysed it

The whole analysis was done by Claude, an AI model, rather than by a research agency or a panel of real users. The table below shows what it did.

STEP	WHAT CLAUDE DID	OUTPUT
Self-analysis of the live app	Opened every screen of the real staging app, counted the buttons, sections and duplicate paths, and marked each one keep, merge or remove.	Simplification plan (25 Oct), second audit (26 Oct)
Simulated user research	Played six different first-time users, used the real app as each of them, and answered a sequenced user-test questionnaire at every step.	Retention simulation (25 Oct)
Deep research	Compared the findings with published retention figures for health and wellness apps, and built a model that forecasts day 1, 7 and 30 return rates for each suggested fix.	The forecasts in section 3
Build and verify	Implemented the approved fixes, re-ran the same six users on the new version, and checked that nothing else changed before production.	Live in production (27 Oct)

In more detail: Claude set up six realistic first-time users with different needs: trouble sleeping, work stress, anxiety with only five minutes to spare, exam focus, an experienced meditator, and someone recovering from burnout. Each one used the real app from a fresh browser, entering a different way (typing on Home, tapping a feeling, pressing Play, signing in first, skipping the setup). Every tap and screen was recorded.

Claude then answered the questions a real user test would ask at each step: was it easy, did it understand me, do I trust what it shows, would I come back tomorrow. A simple model turns those answers into a forecast of how many people return after 1, 7 and 30 days, checked against typical numbers for health and wellness apps.

Because the users were simulated by AI, two kinds of numbers appear in this report. MEASURED means it happened on the real app. PREDICTED means it comes from the model and still has to be confirmed with real people.

2. Before, the suggestion, and what is live now

Seven moments that decide whether a new user stays. Each shows the old screen and today's production screen.

Their own words are used

BEFORE

Someone typed "I can't fall asleep, my mind keeps racing", signed in, and was asked their goal and feelings again. Their sentence was then dropped.

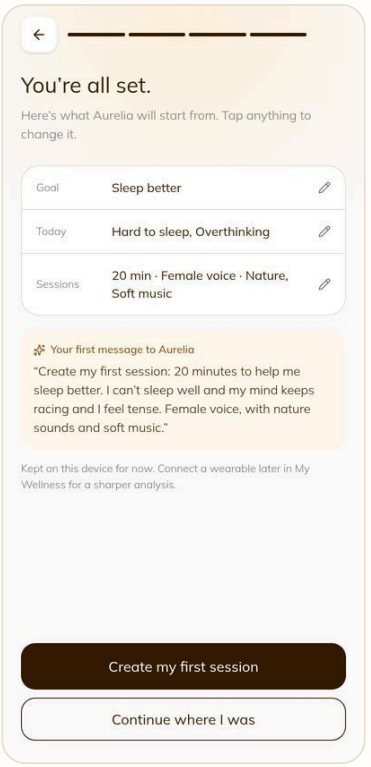

SUGGESTION

Read the goal from what they wrote and go straight to a short summary with one button.

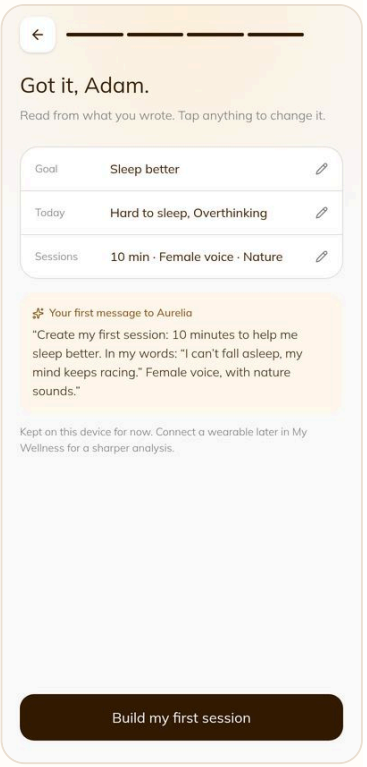

NOW

"Got it, Adam. Read from what you wrote." The summary is filled in and their words go into the first message. LIVE

BEFORE

NOW

A conversation of their own

BEFORE

5 of 6 test users landed in a sample conversation about someone else's sleep score, including a message "they" had supposedly written.

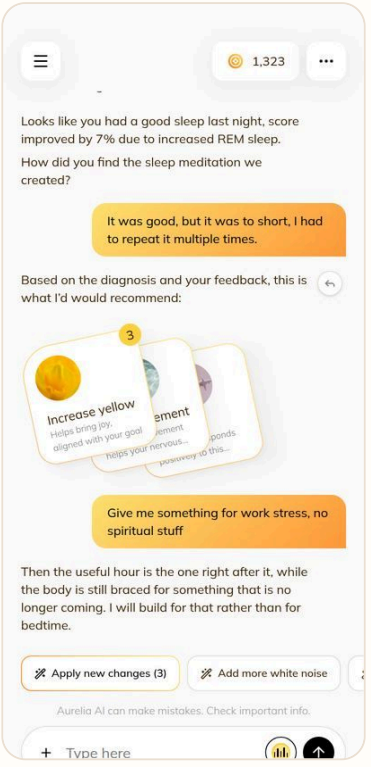

SUGGESTION

Every first visit starts an empty conversation that belongs to the user.

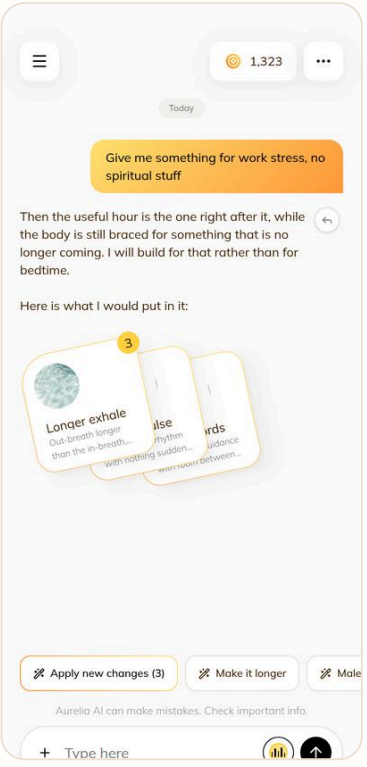

NOW

Every entry point opens their own conversation, whichever way they came in. LIVE

BEFORE

NOW

A first session for their goal, with no early paywall

BEFORE

Everyone got the same "Sleep meditation v1.3" with yellow colours and 432 Hz, even after asking for "no spiritual stuff". Three of six were told their edits were paused after one message.

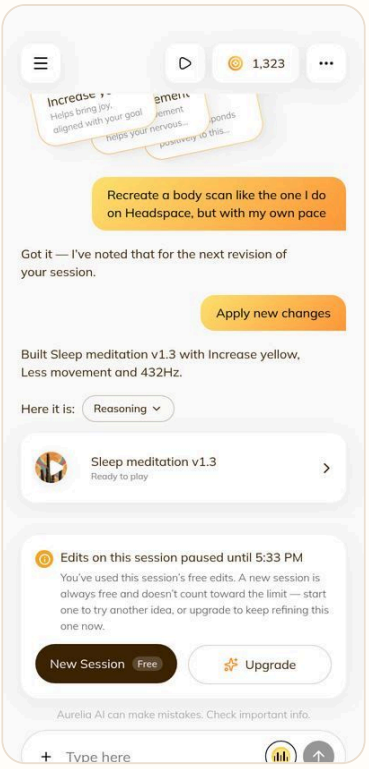

SUGGESTION

Propose changes that match the goal and the choices just made. Count the free limit only after the first session.

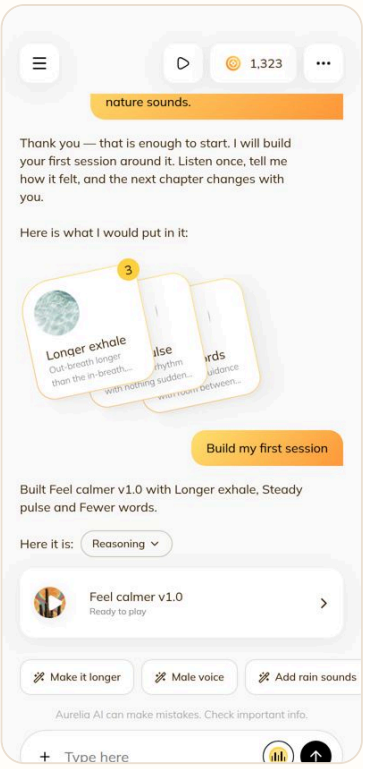

NOW

The session is named after the goal ("Feel calmer v1.0") with matching changes, and the first build happens automatically. No limit before it. LIVE

BEFORE

NOW

Honest results, and a reason to come back

BEFORE

Before pressing play, the player said "Great Progress! +3% since yesterday" and drew three chapters of improvement. None of it was real.

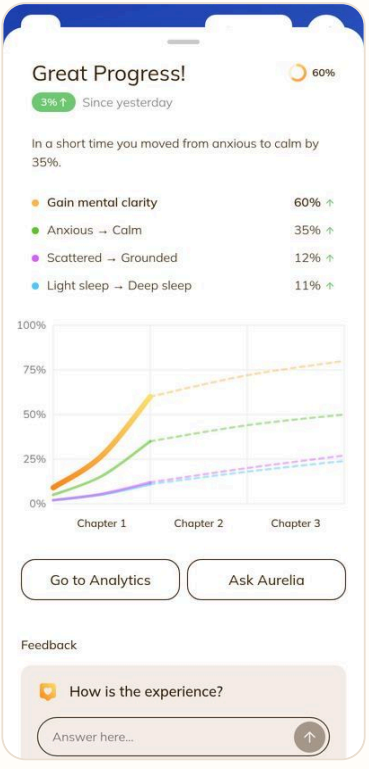

SUGGESTION

Ask "How do you feel now?" (one tap), then promise the next chapter and offer a reminder.

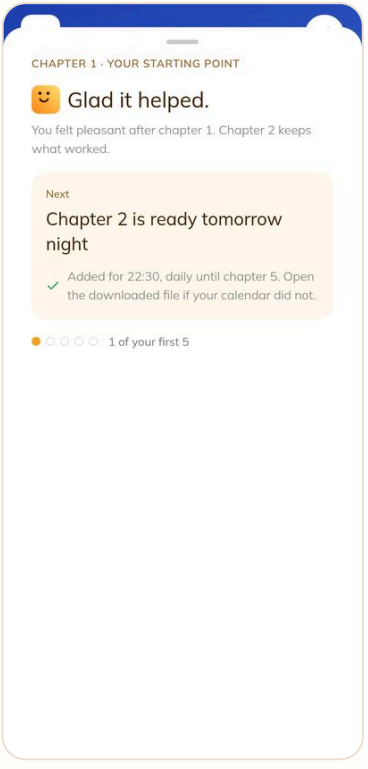

NOW

One-tap check-in, then "Chapter 2 is ready tomorrow night" with a calendar reminder at a time that fits the goal (22:30 for sleep). LIVE

BEFORE

NOW

Home waits for them

BEFORE

After the first session, Home was the same sign-up page a stranger sees. Nothing said what to do next.

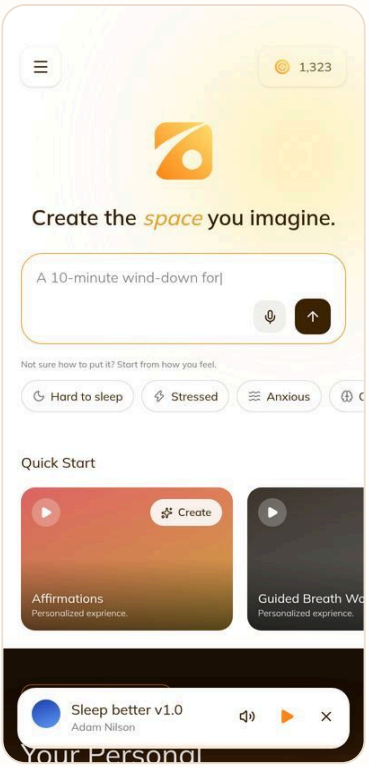

SUGGESTION

Lead with the next chapter, say why it changed, and remove the sales pitch for signed-in users.

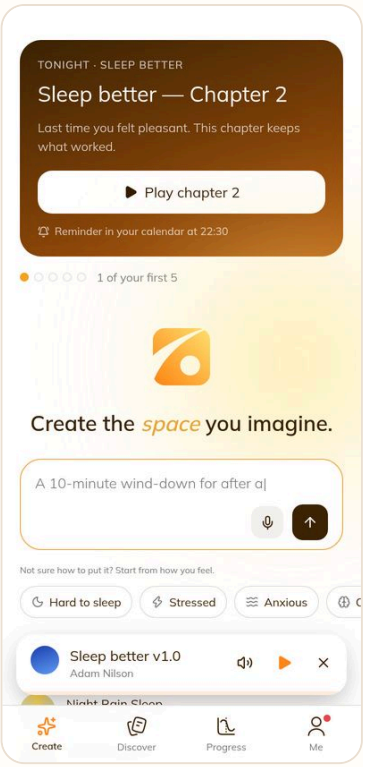

NOW

"Tonight · Sleep better, Chapter 2" with one Play button and a five-chapter track. LIVE

BEFORE

NOW

Four tabs instead of a hidden menu

BEFORE

The main navigation was behind a menu button, with nine items. The coin balance was in about ten headers.

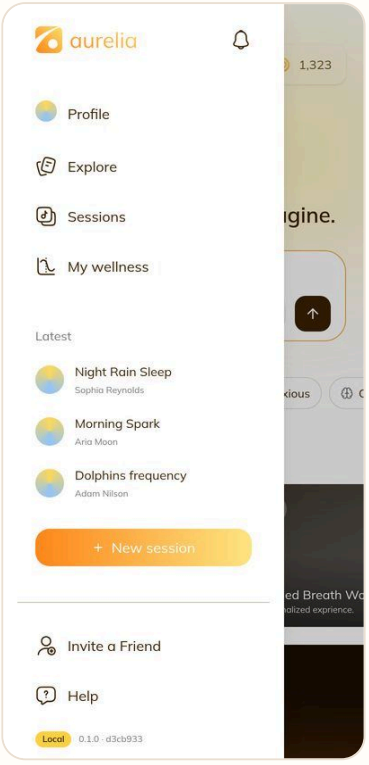

SUGGESTION

Four tabs for the four core features (Create, Discover, Progress, Me), and everything about the account in Me.

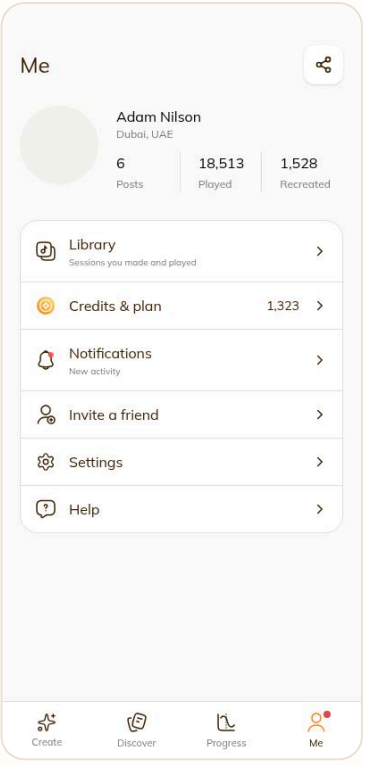

NOW

Four tabs always visible. Me holds Library, Credits & plan, notifications, invite, settings and help. LIVE

BEFORE

NOW

One list of changes in the chat

BEFORE

Three ways to change a session, from two lists with two different scores for the same change (12% and 3%).

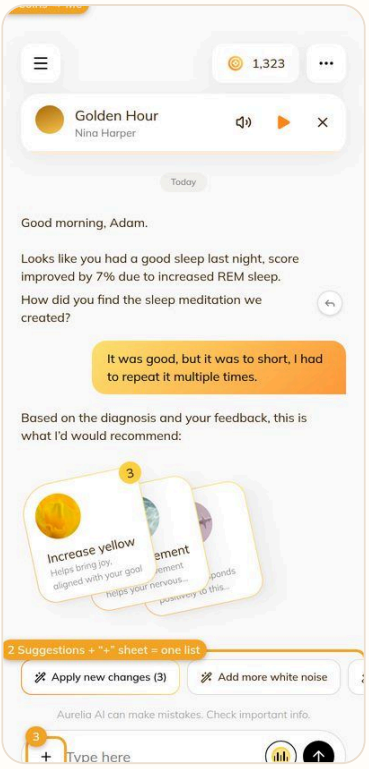

SUGGESTION

One list, with Aurelia's suggestions already picked at the top, and one score each.

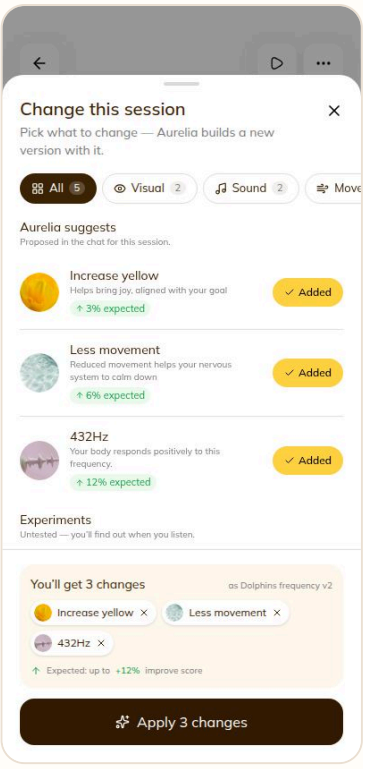

NOW

Tapping the suggestions opens a single "Change this session" list. LIVE

BEFORE

NOW

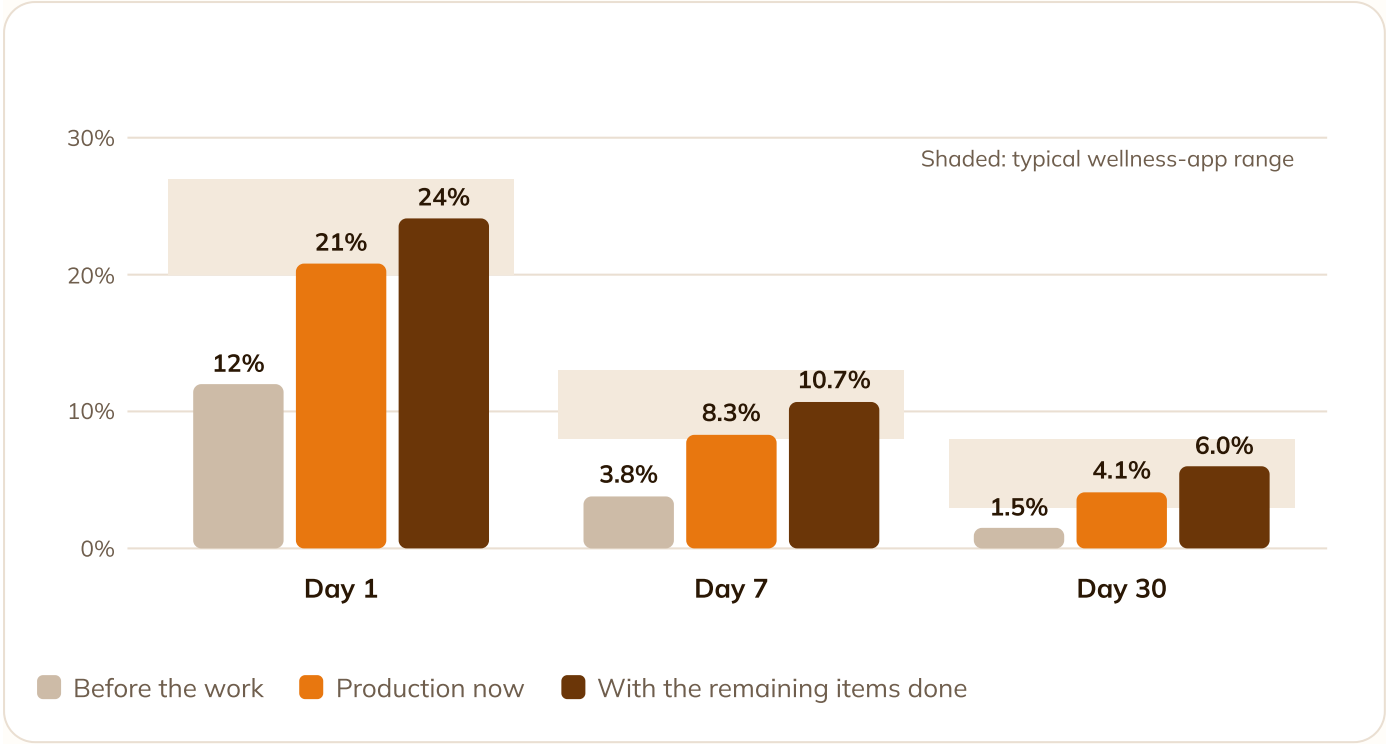

3. Impact

Measured on the real app MEASURED

TEST USER	NEED	BEFORE	NOW
Maya	Can't sleep	14 taps; her words lost; invented progress	5 taps; "Sleep better" built from her words; check-in and reminder
Sari	Anxious, 5 minutes	13 taps; off-topic reply; paywall on message one	6 taps; "Feel calmer" session; no paywall
Tom	Burnout, from his therapist	15 taps; answered as if he asked about focus	6 taps; "Regulate my body" session
Raka	Work stress, skeptical	Sample conversation; watch and calendar "connected" without asking	His own conversation; nothing connected until he chooses
Dewi	Experienced meditator	Asked for a body scan, got "Sleep meditation v1.3"	Gets a body-scan session for her goal
Leo	Exam focus	Pressed Play, got a sign-in wall; never heard a sound	Pressing Play plays straight away

Expected retention PREDICTED

Share of all new users who come back *and listen or create* on day 1, 7 and 30. The shaded band is the usual range for health and wellness apps.

How to read this. Before the work, Aurelia sat below the usual range for wellness apps on every day. Production now should sit at the lower edge of that range, about twice the old return rate. Finishing the remaining items (next section) should bring it into the middle of the range.

These are forecasts from a model built on simulated users, not real people. Use them to choose what to do next, not as numbers to promise. The ranges around them are wide.

4. What is not done yet

ITEM	WHY IT MATTERS	STATUS
Progress tab shows the user's own results	It still shows sample results ("Great Progress 60%") that are not the user's. This is the last place the app shows invented progress.	PROPOSED (S1)
Staying signed in after closing the page	Today every visit starts signed out. Without this, we cannot measure real retention.	DECISION NEEDED
A short test with 8–12 real users	Turns the forecast above into real numbers. Suggested pass line: day 1 at least 25%, day 7 at least 10%, day 30 at least 5%.	NOT STARTED
Push reminders and real AI replies	The reminder is a calendar file for now, and replies after the first message are still demo text. Both need the backend.	NEEDS BACKEND
Further simplification (S2–S7)	Fewer buttons on Create and Discover, one Credits & plan page, one Recreate button. Sent to users for feedback.	WAITING ON FEEDBACK
Design polish in Figma, and the mobile app	The new screens follow our drafts and existing styles. A designer's pass and the Flutter app should follow.	NOT STARTED

5. Decisions needed from you

1. Keep users signed in?

Needed before any real retention number can be trusted. Claude recommends yes, at least for the test.

2. Run the 8–12 person test?

About two weeks including the day-7 follow-up. It confirms or corrects every forecast in this report.

3. Show users their own progress (S1)?

A small change that removes the last invented numbers. Claude recommends doing it next.
